High-Precision Values of the Gamma Function and of Some Related Coefficients

By Arne Fransén and Staffan Wrigge

Abstract. In this paper we determine numerical values to 80D of the coefficients in the Taylor series expansion $\Gamma^m(s+x) = \sum_0^\infty g_k(m, s)x^k$ for certain values of m and s and use these values to calculate $\Gamma(p/q)$ $(p, q = 1, 2, \ldots, 10; p < q)$ and $\min_{x>0}\Gamma(x)$ to 80D. Finally, we obtain a high-precision value of the integral $\int_0^\infty(\Gamma(x))^{-1}\,dx$.

1. Introduction. This paper traces its origin from a wish to determine high-precision values of the integrals $F = \int_0^\infty(\Gamma(x))^{-1}\,dx$ and $\int_n^{n+1}(\Gamma(x))^{-1}\,dx$ because the distribution defined by $G(x) = F^{-1}\int_0^x(\Gamma(t))^{-1}\,dt$ may be useful in reliability theory (Fransén [5]). That can also be approximated by a weighted sum of Gamma Distributions or be seen as a special case of using the Fox H-function as a distribution (Carter and Springer [3]). The integrals in question had not been properly studied (to our great astonishment) before. They were not even mentioned in Nielsen's book on the Gamma function [11]. The closest we came in our literature study was to a paper from 1883 by Bourguet [2]. When establishing high-precision values of the integrals Fransén [4] had to calculate the Riemann Zeta function to 80D for integer values, thereby using formulas of Katayama and Ramanujan [8]. These values might be used for many purposes: to determine the coefficients in the Taylor series expansion of $\Gamma^m(s+x)$ for certain interesting values of m and s, the value of $\min_{x>0}\Gamma(x)$, and many other relevant coefficients.

When carrying out the necessary multiple-precision calculation on our DEC-10 computer we have used a Simula Class HIGHPREC developed by a student, Demetre Betsis, at the University of Stockholm.

2. Numerical Values to 80D of the Coefficients in the Taylor Series Expansion of $\Gamma^m(s+x)$ for Certain Values of m and s.

a. *Basic Formulas.* Let m and s be real numbers, $s > 0$. Consider the Taylor series expansion

$$\Gamma^m(s+x) = \sum_{k=0}^{\infty} g_k(m, s)x^k, \tag{2.1}$$

where

$$g_k(m, s) = \frac{1}{k!}\frac{d^k\Gamma^m(s)}{ds^k}.$$

AMS (MOS) subject classifications (1970). Primary 65D20; Secondary 33A15, 33A25, 65A05.
Key words and phrases. Special functions, Gamma function, Riemann Zeta function.

The coefficients $g_k(m, s)$ may be obtained recursively if we apply Leibniz' differentiation formula to the identity

$$\frac{d\Gamma^m(s)}{ds} = m\psi(s)\Gamma^m(s), \tag{2.2}$$

where $\psi(s)$ is the Psi function $(= \dot{\Gamma}(s)/\Gamma(s))$. We state the main result in the following

THEOREM. *Let m and s be real numbers, $s > 0$. The coefficients $g_k(m, s)$ in the Taylor series expansion*

$$\Gamma^m(s + x) = \sum_{k=0}^{\infty} g_k(m, s)x^k$$

are obtained from the recursion formula

$$(n + 1)g_{n+1}(m, s) = m \sum_{k=0}^{n} (-1)^{k-1} g_{n-k}(m, s)h_k(s),$$

where $h_k(s)$ $(k = 1, 2, \ldots)$ is the Hurwitz Zeta function

$$h_k(s) = \sum_{n=0}^{\infty} \frac{1}{(s + n)^{k+1}}$$

and

$$h_0(s) = -\psi(s) = \lim_{n=\infty} \left(\sum_{k=0}^{n} \frac{1}{s + k} - \ln(n) \right),$$

with the initial value $g_0(m, s) = \Gamma^m(s)$.

A similar result can partly be found in Nielsen's book [11]. We now apply the theorem to some special cases.

b. *Special Cases.* Choosing $s = 1$, we get $g_0(m, 1) = 1$ and $h_0(1) = \gamma$, the Euler constant. Further, we then have $h_k(1) = \zeta(k + 1)$, the Riemann Zeta function, for $k = 1, 2, \ldots$. The computation of values of $\zeta(k)$ for even values of k is straightforward, while we use the Ramanujan formula as described in [8] to compute them in the odd case. In Table I we present these values to 80D for k up to 51.

Putting $m = -1$ and denoting $a_{k+1} = g_k(-1, 1)$, we compute the coefficients using the recursion formula. In Table II we present the values of a_k obtained to 80D for k up to 52. Note that a_k approaches zero very fast. We prove that $\lim_{k=\infty} a_k = 0$ below. We have not been able to derive an approximate expression of a_k or to explain the rather irregular occurrences of plus and minus signs. Already for moderate sizes of s, however, the expansion is properly alternating. Similarly when choosing $m = 1$ and denoting $b_{k+1} = g_k(1, 1)$ we get the values of b_k presented in Table III. We prove also that $\lim_{k=\infty} g_{2k}(1, 1) = 1$ and $\lim_{k=\infty} g_{2k+1}(1, 1) = -1$ below.

Finally, choosing $s = 3/2$, we get $-h_0(s) = \psi(s) = 2 - \gamma - 2 \ln 2$ and $h_k(s) = (2^{k+1} - 1)\zeta(k + 1) - 2^{k+1}$ (see [1]) for $k = 1, 2, \ldots$. We denote for $m = 1$, $c_{k+1} = g_k(1, 3/2)$ and for $m = -1$, $d_{k+1} = g_k(-1, 3/2)$, and present the values of c_k and d_k in Tables IV and V. Note that $g_k(1, 3/2) \approx (-1)^k(2/3)^{k+1}$ and $\lim_{k=\infty} g_k(-1, 3/2) = 0$.

Some of the results presented in Tables I–V have partly been published previously. A paper by J. W. Wrench [13] gives the coefficients a_k to 31D for $k = 2(1)41$. Last-figure corrections appeared in *Math. Comp.*, v. 27, 1973, pp. 681–682, MTE 505. A. H. Morris has compiled two unpublished tables, deposited in the UMT file. The first one, [9], gives $\zeta(k)$ to 70D for $k = 2(1)90$. The second one, [10], includes a tabulation of a_k to 70D for $k = 1(1)73$.

c. *A Draft Proof.* In the text (Section 2b) it is remarked that $\lim_{k=\infty} a_k = 0$ and that $\lim_{k=\infty} g_{2k}(1, 1) = -\lim_{k=\infty} g_{2k+1}(1, 1) = 1$.

By using ordinary residue calculus one sees that

$$\frac{1}{2\pi i}\int z^{-k}\frac{1}{\Gamma(z)}\,dz = a_{k-1}, \tag{2.3}$$

where the integration is carried out around $|z| = 1$. We put $z = e^{i\theta}$. Then

$$a_k = \frac{1}{2\pi}\int_0^{2\pi}(\cos(k\theta) - i\sin(k\theta))\frac{1}{\Gamma(e^{i\theta})}\,d\theta. \tag{2.4}$$

Using a well-known lemma of Riemann-Lebesgue, one gets $\lim_{k=\infty} a_k = 0$. To prove the other results one starts with the identity

$$\Gamma(s) = \int_0^\infty x^{s-1}e^{-x}\,dx = R_1(s) + R_2(s), \tag{2.5}$$

where

$$R_1(s) = \int_0^1 x^{s-1}e^{-x}\,dx = \sum_{k=0}^\infty \frac{(-1)^k}{(s+k)k!}$$

and

$$R_2(s) = \int_1^\infty x^{s-1}e^{-x}\,dx.$$

Differentiating Eq. (2.5) n times with respect to s, we get

$$\Gamma^{(n)}(s)\frac{1}{n!} = \sum_{k=0}^\infty \frac{(-1)^{k+n}}{(s+k)^{n+1}k!} + \frac{R_2^{(n)}(s)}{n!}. \tag{2.6}$$

When $s = 1$ and $n \longrightarrow \infty$ "everything" in the right-hand side of Eq. (2.6) approaches zero except the term $(-1)^n$. Q.E.D.

3. Numerical Values to 80D of $\Gamma(p/q)$; $p, q = 1, 2, \ldots, 10$, $p < q$.

a. *By Taylor Series Expansions.* We shall calculate in all 32 different values $\Gamma(p/q)$, where $p/q \in I$ and $I = I_1 \cup I_2 \cup I_3 \cup I_4 \cup I_5$, where

$$I_1 = \left\{\frac{1}{10}, \frac{1}{9}, \frac{1}{8}, \frac{1}{7}, \frac{1}{6}\right\},$$

$$I_2 = \left\{\frac{1}{5}, \frac{2}{9}, \frac{1}{4}, \frac{2}{7}, \frac{3}{10}\right\},$$

$$I_3 = \left\{\frac{1}{3}, \frac{3}{8}, \frac{2}{5}, \frac{3}{7}, \frac{4}{9}, \frac{1}{2}, \frac{5}{9}, \frac{4}{7}, \frac{3}{5}, \frac{5}{8}, \frac{2}{3}\right\},$$

$$I_4 = \left\{\frac{7}{10}, \frac{5}{7}, \frac{3}{4}, \frac{7}{9}, \frac{4}{5}\right\},$$

$$I_5 = \left\{\frac{5}{6}, \frac{6}{7}, \frac{7}{8}, \frac{8}{9}, \frac{9}{10}, \frac{1}{1}\right\}.$$

We use the Taylor series expansions we have, viz.

$$f(x) = \frac{1}{\Gamma(1+x)} = \sum_{k=0}^{\infty} g_k(-1, 1)x^k \tag{3.1}$$

and

$$g(x) = \frac{1}{\Gamma(3/2+x)} = \sum_{k=0}^{\infty} g_k\left(-1, \frac{3}{2}\right)x^k. \tag{3.2}$$

We have to calculate $xf(x)$ and $(x + ½)g(x)$ with a precision a little greater than $0.5 \cdot 10^{-80}$, whereupon we invert. Therefore, we must have

$$|g_{51}(-1, 1)|x^{52} \lesssim 0.5 \cdot 10^{-80}, \qquad |½g_{51}(-1, 3/2)||x|^{51} \lesssim 0.5 \cdot 10^{-80}.$$

The corresponding values of x are $0 < x < 0.1970$ and $|x| < 0.1964$. If we also allow negative values of x in $f(x)$, we get $-0.1908 < x < 0$.

We can hereby calculate the following values:

(3.3) with $xf(x)$ $\quad \Gamma\left(\frac{p}{q}\right)$ where $\frac{p}{q} \in I_1$: $x = \frac{p}{q}$ in Eq. (3.1),

(3.4) with $(x + ½)g(x)$ $\quad \Gamma\left(\frac{p}{q}\right)$ where $\frac{p}{q} \in I_3$: $x + ½ = \frac{p}{q}$ in Eq. (3.2),

(3.5) with $f(x)$ $\quad \Gamma\left(\frac{p}{q}\right)$ where $\frac{p}{q} \in I_5$: $1 + x = \frac{p}{q}$ in Eq. (3.1).

The values $\Gamma(p/q)$ where $p/q \in I_2 \cup I_4$ cannot be calculated in this simple way. For these missing values we use the duplication formula

$$\Gamma(2x)\sqrt{\pi} = 2^{2x-1}\Gamma(x)\Gamma(x + ½). \tag{3.6}$$

The 32 values of $\Gamma(p/q)$ appear in Table VII.

b. *By Elliptic Integrals.* As is shown by Wrigge [14]–[16] and Glasser and Wood [7] and many others, there is a close relationship between certain values of the gamma function and the complete elliptic integral $K(t)$. The easiest way of getting a good value of $K(t)$ is to use the arithmetic-geometric mean $M(t)$ (see [1]), which will give an accurate value of $K(t)$ to at least 80D in less than 10 steps. We have

$$K(t) = \frac{\pi}{2M(t)}. \tag{3.7}$$

It is, e.g., known that (Fransén [4])

$$\Gamma^2\left(\frac{1}{4}\right) = 4\sqrt{\pi}K\left(\frac{1}{\sqrt{2}}\right), \tag{3.8}$$

$$\Gamma^2\left(\frac{1}{8}\right) = 16K(\sqrt{2} - 1)2^{-3/4}\Gamma\left(\frac{1}{4}\right). \tag{3.9}$$

By using the duplication and reflection formulas for the Gamma function (see [1]) it is possible to get easy-to-calculate expressions for all $\Gamma(p/8)$, $p = 1, 2, \ldots, 8$. Such values are presented to 80D in [4]. Similar results hold for $\Gamma(p/6)$ (see [7]). The values thus calculated agree excellently with the values calculated by the Taylor series method in a. or by other methods as presented in [6].

4. Numerical Values to 80D of x_0 and $\Gamma(x_0) = \min_{x>0}\Gamma(x)$. Instead of $\min_{x>0}\Gamma(x)$ we study $\max_{x>0}(\Gamma(x))^{-1}$ and, thereby, use the Taylor series expansion

$$g(x) = \frac{1}{\Gamma(3/2 + x)} = \sum_{k=0}^{\infty} g_k\left(-1, \frac{3}{2}\right)x^k. \tag{4.1}$$

By making a more and more refined tabulation of $g(x)$ we managed to get a value of x_0 to 37D and of $\min \Gamma(x)$ to 74D. In order to get a better value of x_0 we studied

$$\dot{g}(x) = \sum_{k=1}^{\infty} kg_k\left(-1, \frac{3}{2}\right)x^{k-1}, \tag{4.2}$$

and then made use of "repeated" inverse Bessel interpolation. We thus got

$$\begin{aligned} x_0 = 1.\ & 46163\ 21449\ 68362\ 34126 \\ & 26595\ 42325\ 72132\ 84681 \\ & 96204\ 00644\ 63512\ 95988 \\ & 40859\ 87864\ 40353\ 80181 \end{aligned} \tag{4.3}$$

and

$$\begin{aligned} \Gamma(x_0) = 0.\ & 88560\ 31944\ 10888\ 70027 \\ & 88159\ 00582\ 58873\ 32079 \\ & 51533\ 66990\ 34488\ 71200 \\ & 16587\ 51362\ 27417\ 39635. \end{aligned} \tag{4.4}$$

5. Numerical Values to 60D of $\int_n^{n+1}(\Gamma(x))^{-1}\,dx$ ($n = -10, -9, \ldots, 48$) and $\int_0^\infty(\Gamma(x))^{-1}\,dx$. The original problem for this paper was to determine a high-precision value of the integral $F = \int_0^\infty(\Gamma(x))^{-1}\,dx$ (named Fransén's constant in H. P. Robinson's extensive file of mathematical constants). In [4] Fransén did that using the Euler-Maclaurin formula and got the value of F to 65D. Here we will use the Taylor series methods in Section 2 to calculate $\int_n^{n+1}(\Gamma(x))^{-1}\,dx$ for $n \geqslant 0$.

Using routine manipulation, we get

$$\begin{aligned} \int_n^{n+1}(\Gamma(x))^{-1}\,dx = & \int_0^{1/4}(\Gamma(x+n))^{-1}\,dx \\ & + \int_{-1/4}^{+1/4}(\Gamma(x+n+½))^{-1}\,dx \\ & + \int_{-1/4}^{0}(\Gamma(x+n+1))^{-1}\,dx. \end{aligned} \tag{5.1}$$

But

$$\int_v^u (\Gamma(s+x))^{-1}\,dx = \sum_{k=0}^{\infty} g_k(-1, s)\,\frac{u^{k+1} - v^{k+1}}{k+1}. \tag{5.2}$$

Using the methods in Section 2 and/or some simpler recurrence relations, the coefficients $g_k(-1, n)$ and $g_k(-1, 3/2 + n)$ were calculated for the necessary values of n and the integration carried out. The results to 60D appear in Table VI.

To calculate $\int_n^{n+1}(\Gamma(x))^{-1}\,dx$ for $n < 0$ we used Eq. (5.1) valid also for $n < 0$. Furthermore,

$$\frac{1}{\Gamma(-n+x)} = x(x-1)(x-2)\ldots(x-n)\,\frac{1}{\Gamma(1+x)} \tag{5.3}$$

and

$$\frac{1}{\Gamma(-n+\tfrac12+x)} = (\tfrac12+x)(-\tfrac12+x)\ldots(-n+\tfrac12+x)\,\frac{1}{\Gamma\left(\frac{3}{2}+x\right)}. \tag{5.4}$$

Using the Eqs. (5.3), (5.4) and the Taylor series expansions of $(\Gamma(1+x))^{-1}$ and $(\Gamma(3/2+x))^{-1}$ we calculated the integrals also for negative values of n. The results to 60D are presented in Table VI.

6. Tables. In this section we present the tables previously mentioned, i.e.,

I. The values of γ, the Euler constant and $\zeta(k)$, $k = 2, 3, \ldots, 51$, the Riemann Zeta function, to 80D.

II. The coefficients $g_k(-1, 1)$ in the Taylor series expansion $(\Gamma(1+x))^{-1} = \Sigma_0^\infty g_k(-1, 1)x^k$ to 80D. Note that $a_{k+1} = g_k(-1, 1)$.

III. The coefficients $g_k(1, 1)$ in the Taylor series expansion $\Gamma(1+x) = \Sigma_0^\infty g_k(1, 1)x^k$ to 80D. Note that $b_{k+1} = g_k(1, 1)$.

IV. The coefficients $g_k(1, 3/2)$ in the Taylor series expansion $\Gamma(3/2+x) = \Sigma_0^\infty g_k(1, 3/2)x^k$ to 80D. Note that $c_{k+1} = g_k(1, 3/2)$.

V. The coefficients $g_k(-1, 3/2)$ in the Taylor series expansion $(\Gamma(3/2+x))^{-1} = \Sigma_0^\infty g_k(-1, 3/2)x^k$ to 80D. Note that $d_{k+1} = g_k(-1, 3/2)$.

VI. The values of $\int_0^\infty(\Gamma(x))^{-1}\,dx$ and $\int_n^{n+1}(\Gamma(x))^{-1}\,dx$ ($n = -10, -9, \ldots, 48$) to 60D.

VII. The values of $\Gamma(p/q)$, $p, q = 1, 2, \ldots, 10$: $p < q$, to 80D.

Tabulated values are commonly rounded with a last-figure error not exceeding half a unit.

Acknowledgements. For valuable support during this work we want to thank Dr. John W. Wrench, Jr. and Herman P. Robinson.
